## Analysis of biochemical changes in cultivars of black gram, green gram and pea against powdery mildew

**PP Waghmare and Sahera Nasreen**

**Abstract**

Powdery mildew disease of Black gram, Mung bean and Pea are major constrain in the production. The resistance of plants to various pathogens depends on synthesis and level of various defense enzymes like hydrolases; peroxidases and antimicrobial compounds like phytoalexins (Kuc, 1991 *et al* Kauffmann *et al.* 1987; Boiler, 1987; Mauch *et al.*, 1988; Kale and Choudhary 2001, Koche and Choudhary, 2005). Present study focused on visual screening of selected crop cultivars against the powdery mildew and its biochemical correlation with chlorophyll content, sugars, phenols content, PR-proteins and Phytoalexin activities. From the field studies, it was observed that, selected crop were found with powdery mildew incidence. This disease incidence data was correlated with biochemical changes and level of chlorophyll, sugars, phenols, PR-protein and Phytoalexin activities.

**Keywords:** Black gram, Green gram, pea, biochemical changes, disease incidence, powdery mildew

**1. Introduction**

Black gram (*Vigna mungo* (L.) Green gram (*Vigna radiata* (L.) Wilczek), Pea (*Pisum sativum* L.) and. All these selected pulse crops are important as a nutritional value and production point of view but biotic and abiotic diseases are major challenges to control. Minimize the disease incidence and severity. One of biotic disease is powdery mildew causing to Pigeonpea, Green gram, Black gram, Pea and chickpea by the many specialized races of fungal species in the genera *Erysiphe*, *Microsphaera*, *phylactinia*, *podosphaera* and *Uncinula*. Powdery mildew of Black gram (*Vigna mungo* (L.) Green gram (*Vigna radiata* (L.) Wilczek), Pea (*Pisum sativum* L.) are caused by *Erysiphe polygoni* DC, *Erysiphe polygoni* and *Erysiphe pisi* are major diseases.

Infection of this disease can significantly reduce yield (by up to 25%) by reducing photosynthetic leaf area also other biochemical changes in infected leaves compared to health and resistant to this diseases. Sanjay Guleria *et al.* (1997) reported post-infection decrease in chlorophyll a, chlorophyll total chlorophyll and reducing sugar content in the leaves of both resistant (DPP68 and JP71) and susceptible cultivars (Bonneville and Lincoln) of pea against powdery mildew (*E. polygoni*). Baka and Aldesuquy (1992) reported that decrease in reducing sugars in squash affected by powdery mildew caused by *Sphaerotheca fuliginea*. Similarly Awad (2000) reported positive correlation between susceptibility to powdery mildew and leaf sugar content in most cucurbit varieties. Sindhan and Jaglan (1987) reported higher amounts of total phenols in resistant genotypes of ground nut affected by tikka leaf spot as compared to the susceptible ones. Avtar *et al.* (2003) <sup>[1]</sup> observed higher levels of total phenols in resistant genotypes (NLM and HM 350) than susceptible (T8 and HM 65) fenugreek genotypes before and after the appearance of powdery mildew (*E. polygoni*) in artificially inoculated and natural environments.

Dinesh (2009) showed that initially healthy leaves of susceptible variety of Sunflower (Morden) had 1.204 mg/g of total phenols and it was increased to 3.980 mg/g after infection by *E.cichoracearum*. The synthesis of biochemical compounds and their level in plant offer a particular characteristic to it. Presence of various biochemical compounds in plant during its different developmental stages of indicates their importance for their survival. Production and level of plant hormones and some enzymes determine the percentage of germination, growth rate, development and reproduction (Abeles *et al.* 1971; Jones. 2001 and Dangel. 2001). The resistance of plants to various pathogens depends on synthesis and level of various

 research center, Aurangabad,  
 Maharashtra, India

defense enzymes like hydrolases; peroxidases and antimicrobial compounds like phytoalexins (Kuc, 1991 *et al* Kauffmann *et al.* 1987; Boiler, 1987; Mauch *et al.*, 1988; Kale and Choudhary 2001, Koche and Choudhary, 2005). Thus all these reports suggest that the synthesis and level of biochemical compounds in plants play vital role in shaping various traits of all plant species. The objective of this research was to determine the roles of biochemical compounds, in the interaction of selected crops with powdery mildew fungi.

## 2. Material and Methods

### 2.1 Germplasm Procurement and field experiment:

Germplasm Procurement and field experiment: The germplasm of Black gram, Green gram, pea, was procured from Dr. P. D. K. V. Akola and M. P. K. V. Rahuri (MS). Germplasm are used for further sowing in field and in vitro experimentation. In vitro experiment carried out at Department of Botany, Government institute of science, Aurangabad.

### 2.2 Disease incidence and Severity analysis

In all experiments, disease incidence (percentage) and severity were assessed at 2-day intervals. Severity of symptoms on individual plants were rated on a scale from 0–4 according to the percentage of foliage with yellowing or necrosis in acropetal progression: 0 = 0%, 1 = 1–33%, 2 = 34– 66%, 3 = 67–100%, 4 = dead plant. Incidence and severity data (0–4 scale) within a pot were used to calculate a disease intensity index (DII) by the equation:  $DII = [(\sum Si \times Ni) / 4 \times Nt] \times 100$

### 2.3 Estimation of chlorophyll content

About 100 mg of healthy and infected leaf samples of mung bean, chickpea and pea were collected from the field. The chlorophyll was extracted in Dimethyl sulfoxide (DMSO) as described by Hiscos and Israelstan (1979) [10]. The leaf samples were placed in a test tube containing 7 ml DMSO and incubated at room temperature for 24 hours. The extracted liquid was transferred to graduate test tubes and volume was made up to 10 ml with DMSO, and the stock solution was diluted to 50 per cent with DMSO. About 3 ml sample of chlorophyll extract was transferred to cuvette and OD values were read at 645 and 663 nm along with DMSO blank in the spectrophotometer. Chlorophyll content was calculated by formula (Arnon, 1949). Reducing sugars for the leaf samples were estimated by Nelson's modification of Somogyi's method (Nelson, 1944) [16]. Non-reducing sugars were hydrolyzed by using 1 ml 1N H<sub>2</sub>SO<sub>4</sub> and then estimated as in case of reducing sugars to get the total sugars. Non-reducing sugars were calculated by subtracting the reducing sugars from that of total sugars.

### 2.4 Estimation of total phenols

Estimation of total phenols in the plant samples was carried out following Folin-Ciocalteu reagent method.

**Reagents:** Folin - Ciocalteu reagent (FCR) - 1% and Sodium carbonate - 2%

**Procedure:** One ml of alcohol extract was taken in a test tube to which one ml of Folin-ciocalteu reagent was added followed by two ml of sodium carbonate solution. Then the tubes were shaken well and heated on boiling water bath for

exactly one minute and cooled under running tap water. The blue solution was diluted to fifteen ml with water and its absorbance was read at 650 nm in spectrometer. The amount of phenols present was calculated with the help of a standard curve prepared from catechol.

### 2.5 Extraction and PR-protein assay

Chitinase and  $\beta$ -1,3-glucanase were extracted by homogenizing 1g of frozen tissues in 1 ml and ice cold extraction buffer (0.1M Sodium citrate buffer, pH 5), in pre-chilled mortar and pestle. The extract was centrifuged at 10,000 rpm for 15 min. 1ml of supernatant was taken in 1.5 ml centrifuge tube and proteins were precipitated by adding ammonium sulphate to saturation. The precipitated protein were centrifuged at 10,000 rpm for 15 min and supernatant was discarded. The protein palletted resuspended in 1ml extraction buffer and used as enzyme source for glucanase and chitinase activity. The assay of  $\beta$ -1, 3 glucanase was performed according to method given by Kauffmann *et al.*, (1987). The assay mixture was prepared by mixing 0.48 ml of 0.1M Sodium acetate buffer (pH, 5.2), 100  $\mu$ l of enzyme extract, and 200  $\mu$ l Laminarin (Sigma) solution. The mixture was incubated at 37 °C for 3 hrs. Then, 0.5 ml alkaline copper tartrate was added to it and mixture was heated at 100 °C, in the boiling water bath for 5 min. The mixture was then cooled to room temperature and 0.5ml of arsenomolybdate reagent was added to it. After the development of blue color, 3ml of distilled water was added to each sample and absorbance was recorded at 660 nm against the blank containing the enzyme extract and all other reagent except Laminarin. The chitinase activity was analyzed according to the method of Reissig *et al.*, (1954) and Boller *et al.*, (1983) [5]. The enzyme assay mixture contained 100  $\mu$ l of sodium acetate buffer (pH 4.5), 100 $\mu$ l Sodium azide solution, and 200  $\mu$ l colloidal chitin and 100  $\mu$ l enzyme extract. The volume of this enzyme extract was adjusted to 1 ml by extraction buffer and incubated at 37 °C for 3 hrs. Then 100  $\mu$ l of Sodium borate buffer (pH 9.1) was added to it and heated to 100 °C in water bath for 3 min. The mixture was then cooled in tap water and centrifuged at 1000 rpm for 5 min. The clear supernatant was collected and to it 3 ml of DMAB reagent was added. The mixture was then incubated for 20 min at 37 °C. The absorbance was recorded immediately at 585 nm against the blank containing all the reagents and enzyme except chitin.

### 2.6 Phytoalexin analysis

In this investigation the accumulation of phytoalexin metacarpi, in response to natural infection by powdery mildew fungi, was analyzed, by high performance liquid chromatography (HPLC) following the method adopted by Edward and Strange (1991). The phytoalexin was also analyzed in infected and healthy leaves as well as in seedlings of different cultivars. One gram of sample was extracted with 5 ml of 80% methanol. The methanol extract was reduced to 1/4<sup>th</sup> of initial volume, under vacuum and extracted (3x) with ethyl acetate. The pooled ethyl acetate extract was reduced to dryness and contents were dissolved in one-ml acetonitrile. The 20  $\mu$ l acetonitrile extract was injected for quantitative analysis. The samples were chromatographed on Shimadzu HPLC system with ODS C<sub>18</sub> (Spherosphere) column (4x250 size) maintained at 35 °C temperature. The flow rate of mobile phase (50% aqueous acetonitrile) was 1.5ml/ minute. The medicarpin was

detected at 290 nm using a PDA detector with retention time of 23 minutes. The retention time was determined by co-chromatography of standard obtained from Sigma

### 3. Results and Discussion

The field experiment reveals that cultivar of black gram, BDU-1 and TAU-1 is showed 3% and 19% disease incidence against powdery mildew 50 days after germination respectively. BDU-1 is resistant and TAU-1 is susceptible to powdery mildew. In cultivar of Green gram LGG, K-851 and cultivars of Pea, JP- 71 and Arkel showed that 5%, 37%, 2.7% and 48% disease incidence respectively (Table. 1). On the basis disease incidence index showed that cultivar BDU-1, LGG and JP-71 is resistant against the powdery mildew and TAU-1, K-851 and Arkel is susceptible against the powdery mildew. The chlorophylls loss in resistant and susceptible cultivars of Black gram, Green gram and pea due to development of powdery mildew.

The quantity of chl. a, chl. b and total chlorophyll in healthy and infected leaves. In susceptible Cultivars of selected crops that is TAU-1, K-851 and Arkel, the chl.a content in healthy leaves was 1.77,1.89 and 1.23 mg/g respectively and it has been reduced in infected leaves by powdery mildew that estimate the chl.a 1.2, 0.89 and 0.41 mg/g respectively and in resistant cultivars of selected crop that BDU-1, LGG and JP-71, the chl.a estimated in healthy leaves1.89, 1.98 and 1.81 it has been reduced to 1.71,1.82 and 1.63 mg/g after infection of powdery mildew. Chlorophyll b and total

chlorophyll content in healthy and infected leaves are same trends in resistant and susceptible cultivars leaves (Table 2). The amount total sugars, reducing and non reducing sugars in both healthy and infected leaves of selected crops cultivar were estimated. The estimated data showed that highest total sugar content found in infected leaves compared to healthy also same trends for phenols content (Table.2).The accumulation of phytoalexin and PR-proteins in infected and healthy leaves showed highest value in infected leaves of Resistant and susceptible cultivars than healthy leaves of resistant and susceptible one (table.3&4).

Chlorophyll, sugar, phenols, phytoalexin and PR-protein in plant could be positively correlated with the disease incidence index in case of black gram, green gram and pea of powdery mildew pathosystem. The Similar correlation was reported by Cachinero *et al.* (2002) in three Chickpea cultivars. Koche and Choudhary (2005) <sup>[14]</sup> also reported that the level of PR- protein in Mungbean cultivars could be positively correlated with its resistance status. In 2007, Badere *et al.*, reported the positive correlation of phytoalexin accumulation and resistant status of seven mungbean cultivars. These findings are also supported by the reports of Koche and Choudhary (2011) <sup>[13]</sup>. Balerao and Kothekar (2013) have reported the positive correlation between Resistance of crop with its biochemical content. Khandare (2015). The present study are in accordance with above reports and could be exploited further at molecular level for developing powdery mildew resistant selected crop cultivars.

**Table 1** Disease incidence and disease severity of powdery mildew in each two naturally grown cultivars Green Gram and Pea.

| Crop name  | Cultivar | Number of plant observed | Disease incidence (%) | Resistant Status |
|------------|----------|--------------------------|-----------------------|------------------|
| Black Gram | BDU-1    | 1028                     | 3                     | Resistant        |
|            | TAU-1    | 856                      | 19                    | Susceptible      |
| Green Gram | LGG      | 986                      | 5                     | Resistant        |
|            | K-851    | 587                      | 37                    | Susceptible      |
| Pea        | JP-71    | 867                      | 2.7                   | Resistant        |
|            | Arkel    | 953                      | 48                    | Susceptible      |
